

# The magnetron is dead – long live Solid State RF Technology

K. Werner, pinkRF

# Introduction SSRF technology

- Technology basics
- Differences to magnetrons
- Control:
  - right amount of power,
  - At the right time
  - At the right place
- E.g. leading e.g. to a homogeneously heated specimen

# A classic: Magnetron as energy source in microwave oven or industry

Magnetron

Object heated through absorption of RF Energy

← Closed cavity to localize heating and limit unwanted RF emission

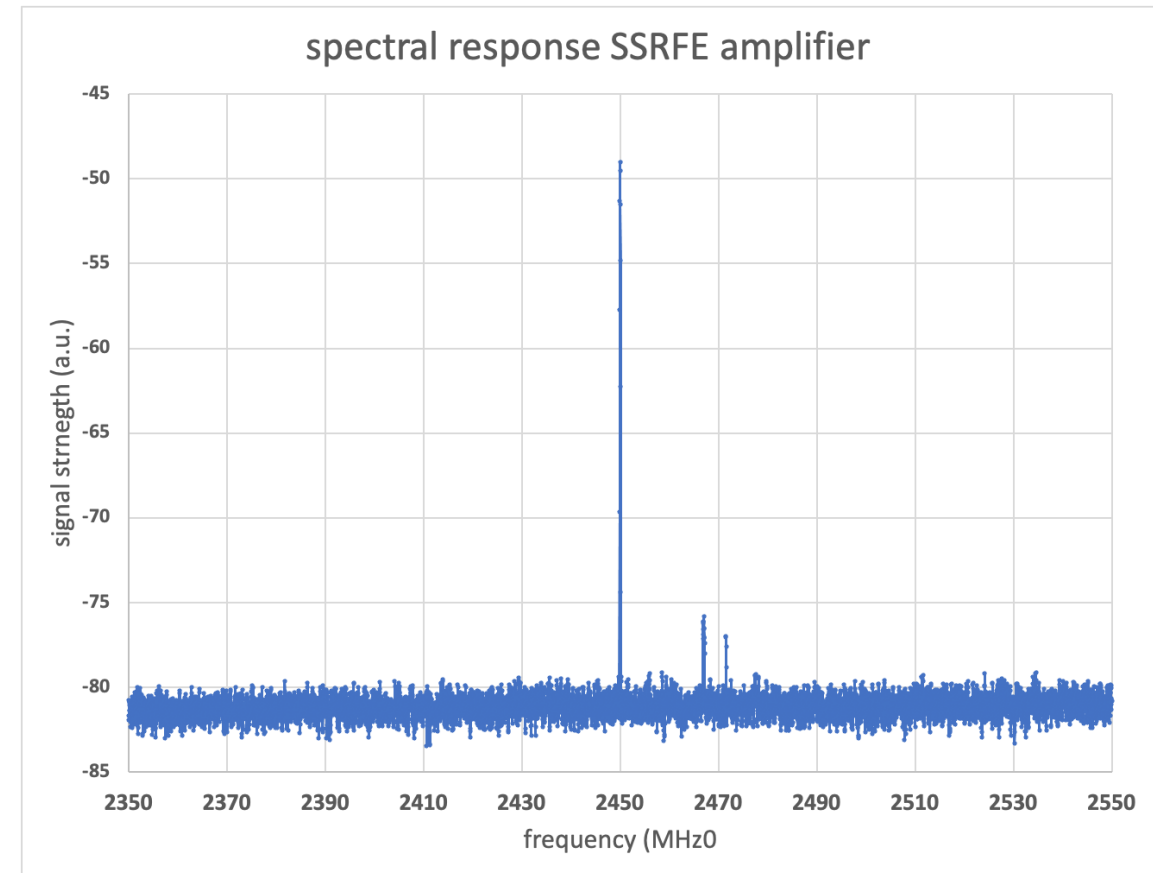

# Magnetron + its spectrum

- Mechano-electrical oscillator
- None to poor spectral control
- Slow power control
- Industrial-grade magnetron systems can be “clean”

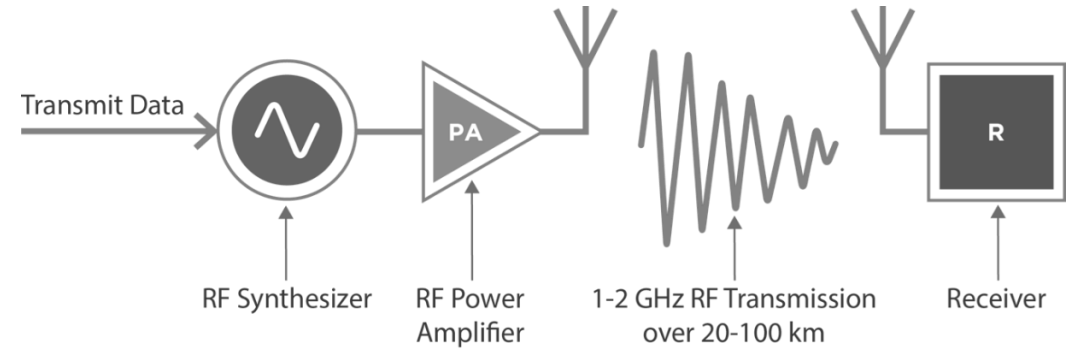

# Solid state generated RF

- Control: just one RF **vector** at a time
  - Precision **frequency, amplitude** and **phase**
  - -> Very clean spectral source
  - reproducible

# Semiconductor-based RF energy -> SSRFE

- Common use solid state RF:

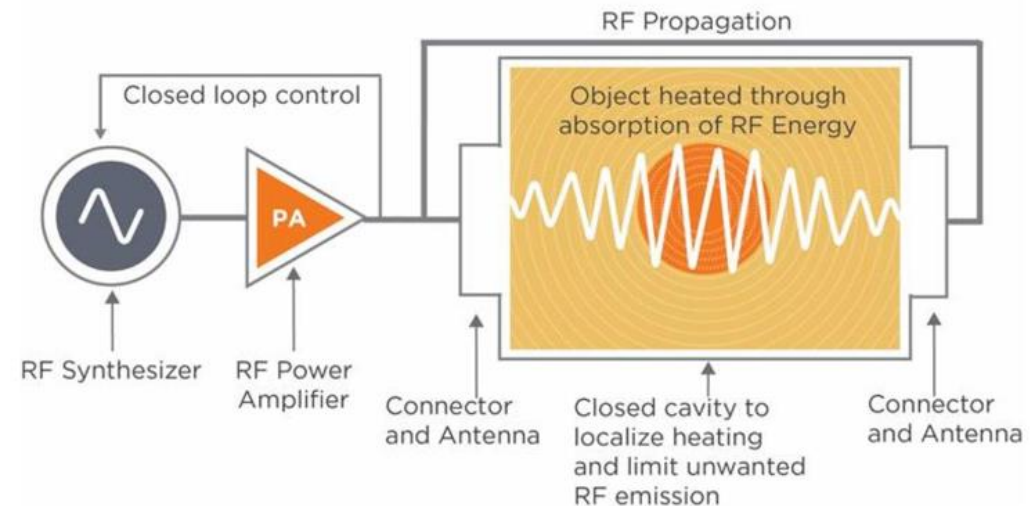

- We'll talk about heating dielectrics with non-ionizing, RF energy!

# SSRFE & feedback

- Generators measure forward and reflected RF power (and phase)
  - Calorimetric process control & quality
  - "Network analyzer" functionality
    - "talk to your load"
- Large dynamic energy range ( $\mu\text{J}$  -> MJ)
  - $\mu\text{s} * \text{W}$  ->  $\text{ks} * \text{kW}$
- Agile!
  - $\mu\text{s}$  timescale
  - Swift response to arcing
  - Electronics and process protection

# Solid-State RF Energy Sources – Characteristics Overview

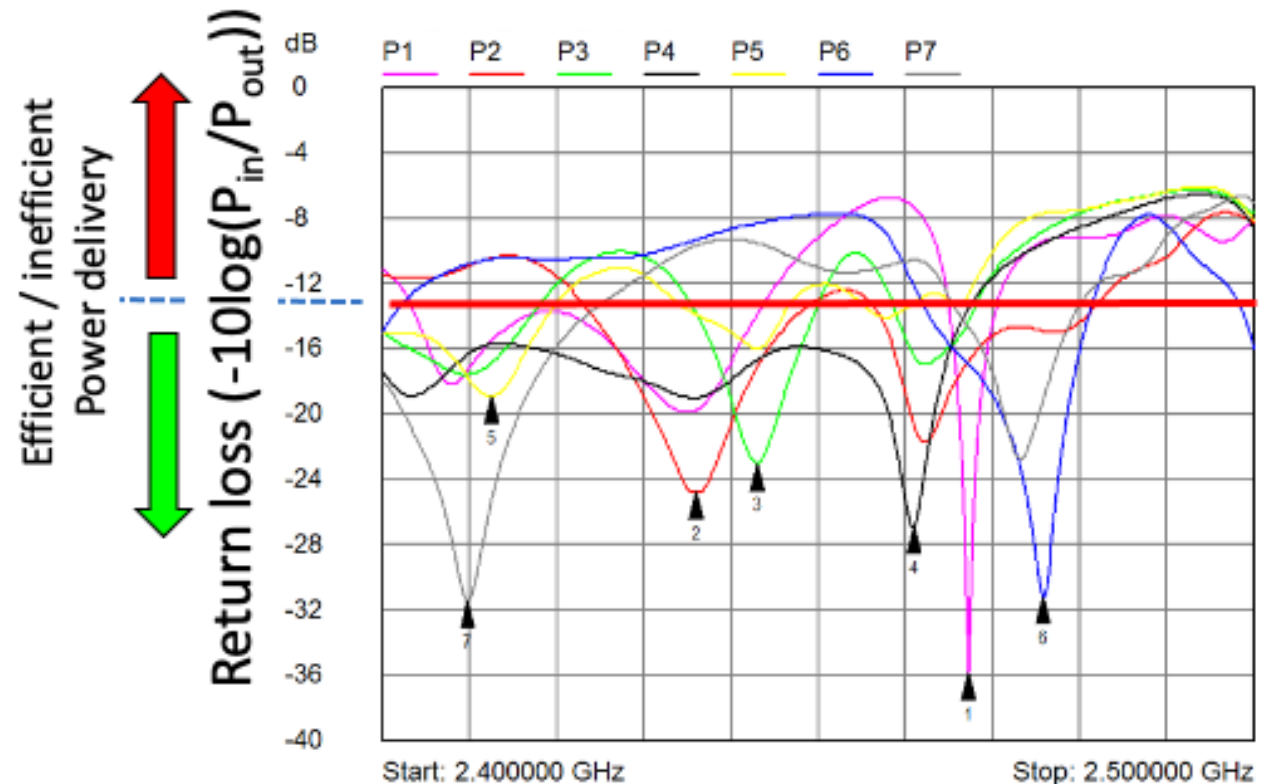

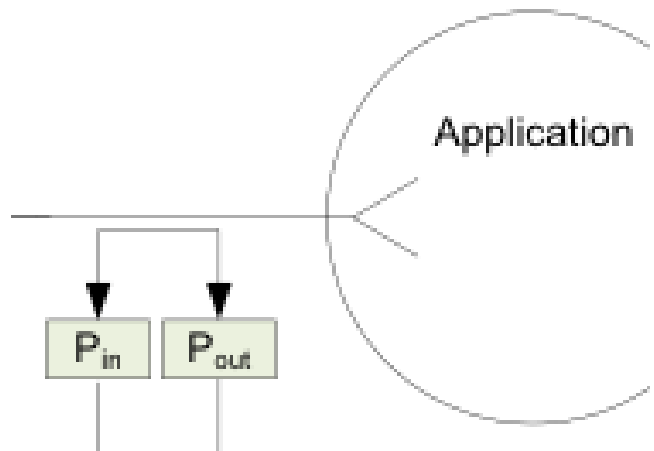

- **Unprecedented control** over RF signal
  - Power, phase, frequency
  - Reproducibility -> “Precision”
    - Can be modeled/simulated
- Feedback
- Effective, and fast reaction to (changing) load conditions
  - Efficient energy delivery, fast shutdown, ...
- Low-voltage electronics
- Small form factor; flexible hardware partitioning
- Solid state semiconductor-based reliability
- Electronics cost base enabled
- System efficiency on par with magnetrons

# Precision energy delivered – into the applicator

- EM Energy into the applicator (the active volume with load)
- $P_{\text{delivered}} = P_{\text{out}} - P_{\text{in}}$
- Frequency to tune adaptively -> efficient process
  - situation will change during process
  - -> S11 tracker / “DLL”

# “Focusing or containing” RF energy -> applicators

- “process”- size related to wavelength of radiation
- Irradiate smaller locations / objects of interest through:
  - frequency choice
  - Antenna design
  - Dielectric properties and modifications thereof
  - ...

# Plasma applications – musical torch

# Popcorn popper

# solid state feeding architecture -> power!

- “magnetron” style
  - “single” point source – high to very high power levels
    - combine PA modules “outside”
      - magnetron replacement scenario for existing systems
    - Coherence required!
- “distributed” style
  - multiple feed points, limited power per feed line/PA
  - flexible, distributed, redundant, “optimal” control
  - integration/control issue for large number of generators

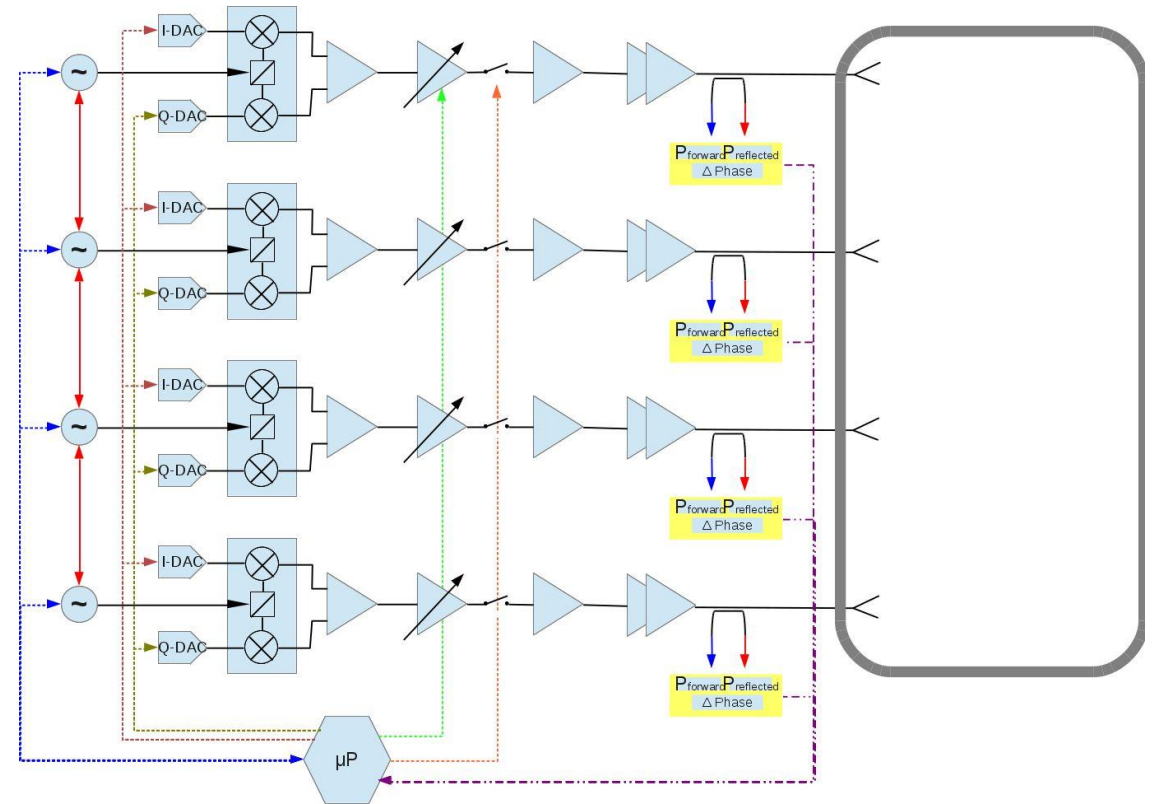

© Orbitfr.com

# Coherence – maintain phase

- Distributed local oscillator
  - Mind phase offsets
  - Mind AM2PM
    - Common mode delta
    - Differential delta
- Possible issues:
  - Power combining problems
  - Agreement simulation with reality
- Application:
  - Hyperthermia treatment

# Hyperthermia treatment

- Superposition of multi-channel wavefronts permit the exact “focus” of maximum energy deposition at the location of the tumor
- Lot of modeling required

# Hyperthermia treatment system

- $\leq 20$  channels

- Antennae in water boluses; boluses in contact with skin

# Sub-ml heater for micro-chemistry

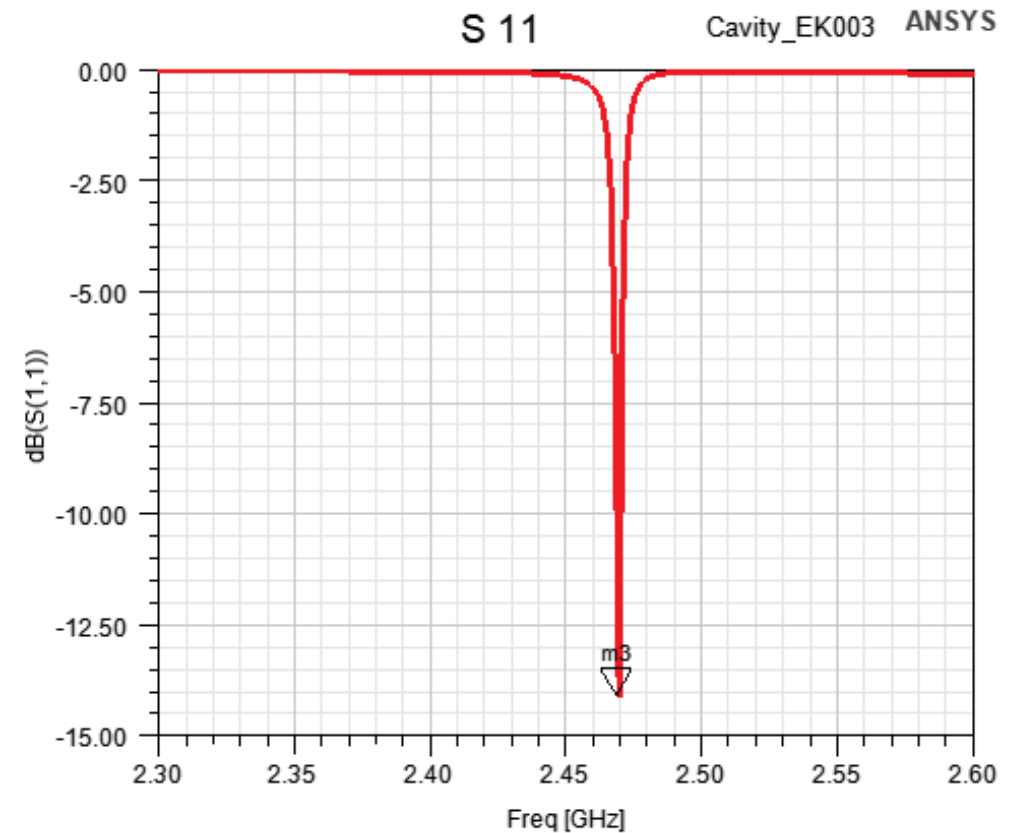

- 20 W, 2.45 GHz RF Generator including signal generator, power amplifier and control unit + Screen
- Static or flow-thru geometry

# 3D-EM Simulation of the Applicator incl. sample tube

- Simulation outcome (with tube)
- $TM_{110}$ -Mode

# RF testing with 20 W

- Heating test up to 90 °C
- Heating rate: 3.9 K/s from 24°C to 90°C

# Conclusions

- Solid State RF:

Predictable energy, timely delivered with laser precision
